

INTRODUCTION TO ALGORITHMS

Lecture 11: Shortest Path Algorithms

Yao-Chung Fan
yfan@nchu.edu.tw

Shortest paths in an edge-weighted digraph

Given an edge-weighted digraph, find the shortest path from s to t .

Shortest path variants

Which vertices?

- **Single source:** from one vertex s to every other vertex.
- Source-sink: from one vertex s to another t .
- All pairs: between all pairs of vertices.

Restrictions on edge weights?

- Nonnegative weights.
- Arbitrary weights.

Cycles?

- No directed cycles.

which variant?

Simplifying assumption. Shortest paths from s to each vertex v exist.

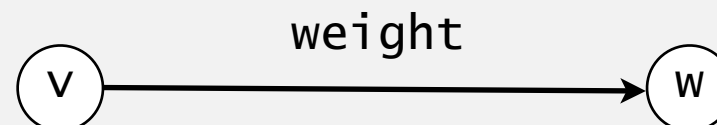

SHORTEST PATHS

- ▶ *APIs*
 - ▶ *shortest-paths properties*
 - ▶ *Dijkstra's algorithm*
 - ▶ *Edge-weighted DAGs*

Weighted directed edge API

```
public class DirectedEdge
```

<code>DirectedEdge(int v, int w, double weight)</code>	<i>weighted edge $v \rightarrow w$</i>
<code>int from()</code>	<i>vertex v</i>
<code>int to()</code>	<i>vertex w</i>
<code>double weight()</code>	<i>weight of this edge</i>
<code>String toString()</code>	<i>string representation</i>

Idiom for processing an edge `e`: `int v = e.from(), w = e.to();`

Weighted directed edge: implementation in Java

Similar to Edge for undirected graphs, but a bit simpler.

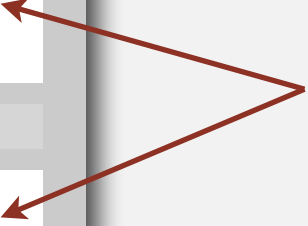

```
public class DirectedEdge
{
    private final int v, w;
    private final double weight;

    public DirectedEdge(int v, int w, double weight)
    {
        this.v = v;
        this.w = w;
        this.weight = weight;
    }

    public int from()
    { return v; }

    public int to()
    { return w; }

    public int weight()
    { return weight; }
}
```

from() and to() replace
either() and other()

Edge-weighted digraph API

```
public class EdgeWeightedDigraph
```

```
    EdgeWeightedDigraph(int V)    edge-weighted digraph with V vertices
```

```
    EdgeWeightedDigraph(In in)    edge-weighted digraph from input stream
```

```
    void addEdge(DirectedEdge e)    add weighted directed edge e
```

```
    Iterable<DirectedEdge> adj(int v)    edges pointing from v
```

```
    int V()    number of vertices
```

```
    int E()    number of edges
```

```
    Iterable<DirectedEdge> edges()    all edges
```

```
    String toString()    string representation
```

Conventions. Allow self-loops and parallel edges.

Edge-weighted digraph: adjacency-lists representation

Edge-weighted digraph: adjacency-lists implementation in Java

Same as EdgeWeightedGraph except replace Graph with Digraph.

```
public class EdgeWeightedDigraph
{
    private final int V;
    private final Bag<DirectedEdge>[] adj;

    public EdgeWeightedDigraph(int V)
    {
        this.V = V;
        adj = (Bag<DirectedEdge>[]) new Bag[V];
        for (int v = 0; v < V; v++)
            adj[v] = new Bag<DirectedEdge>();
    }

    public void addEdge(DirectedEdge e)
    {
        int v = e.from();
        adj[v].add(e);
    }

    public Iterable<DirectedEdge> adj(int v)
    {
        return adj[v];
    }
}
```

← add edge $e = v \rightarrow w$ to
only v 's adjacency list

Single-source shortest paths API

Goal. Find the shortest path from s to every other vertex.

```
public class SP
```

```
    SP(EdgeWeightedDigraph G, int s)    shortest paths from s in graph G
```

```
    double distTo(int v)                length of shortest path from s to v
```

```
    Iterable <DirectedEdge> pathTo(int v)    shortest path from s to v
```

```
    boolean hasPathTo(int v)            is there a path from s to v?
```

```
SP sp = new SP(G, s);
for (int v = 0; v < G.V(); v++)
{
    StdOut.printf( s, v, sp.distTo(v));
    for (DirectedEdge e : sp.pathTo(v))
        StdOut.print(e + " ");
    StdOut.println();
}
```

Single-source shortest paths API

Goal. Find the shortest path from s to every other vertex.

```
public class SP
```

```
    SP(EdgeWeightedDigraph G, int s)    shortest paths from s in graph G
```

```
    double distTo(int v)                length of shortest path from s to v
```

```
    Iterable <DirectedEdge> pathTo(int v)    shortest path from s to v
```

```
    boolean hasPathTo(int v)            is there a path from s to v?
```

```
% java SP tinyEWD.txt 0

SHORTEST PATHS

- ▶ *APIs*
- ▶ *Shortest-paths properties*
- ▶ *Dijkstra's algorithm*
- ▶ *Edge-weighted DAGs*

Data structures for single-source shortest paths

Goal. Find the shortest path from s to every other vertex.

Observation. A **shortest-paths tree** (SPT) solution exists. Why?

Idea. Represent the SPT with two vertex-indexed arrays:

- $\text{distTo}[v]$ is length of shortest path from s to v .
- $\text{edgeTo}[v]$ is last edge on shortest path from s to v .

shortest-paths tree from 0

	edgeTo[]	distTo[]	
0	null	0	
1	5->1 0.32	1.05	$1.05 = 0.32 + 0.35 + 0.38$
2	0->2 0.26	0.26	
3	7->3 0.37	0.97	
4	0->4 0.38	0.38	
5	4->5 0.35	0.73	
6	3->6 0.52	1.49	
7	2->7 0.34	0.60	

parent-link representation

Data structures for single-source shortest paths

Goal. Find the shortest path from s to every other vertex.

Observation. A **shortest-paths tree** (SPT) solution exists. Why?

Consequence. Can represent the SPT with two vertex-indexed arrays:

- `distTo[v]` is length of shortest path from s to v .
- `edgeTo[v]` is last edge on shortest path from s to v .

```
public double distTo(int v)
{ return distTo[v]; }
```

```
public Iterable<DirectedEdge> pathTo(int v)
{
    Stack<DirectedEdge> path = new Stack<DirectedEdge>();
    for (DirectedEdge e = edgeTo[v]; e != null; e = edgeTo[e.from()])
        path.push(e);
    return path;
}
```

e.g., `pathTo(7)`

	edgeTo[]	distTo[]
0	null	0
1	5->1 0.32	1.05
2	0->2 0.26	0.26
3	7->3 0.37	0.97
4	0->4 0.38	0.38
5	4->5 0.35	0.73
6	3->6 0.52	1.49
7	2->7 0.34	0.60

Edge relaxation

Relax edge $e = v \rightarrow w$.

- $\text{distTo}[v]$ is length of shortest **known** path from s to v .
- $\text{distTo}[w]$ is length of shortest **known** path from s to w .
- $\text{edgeTo}[w]$ is last edge on shortest **known** path from s to w .
- If $e = v \rightarrow w$ gives shorter path to w through v , update both $\text{distTo}[w]$ and $\text{edgeTo}[w]$.

$v \rightarrow w$ successfully relaxes

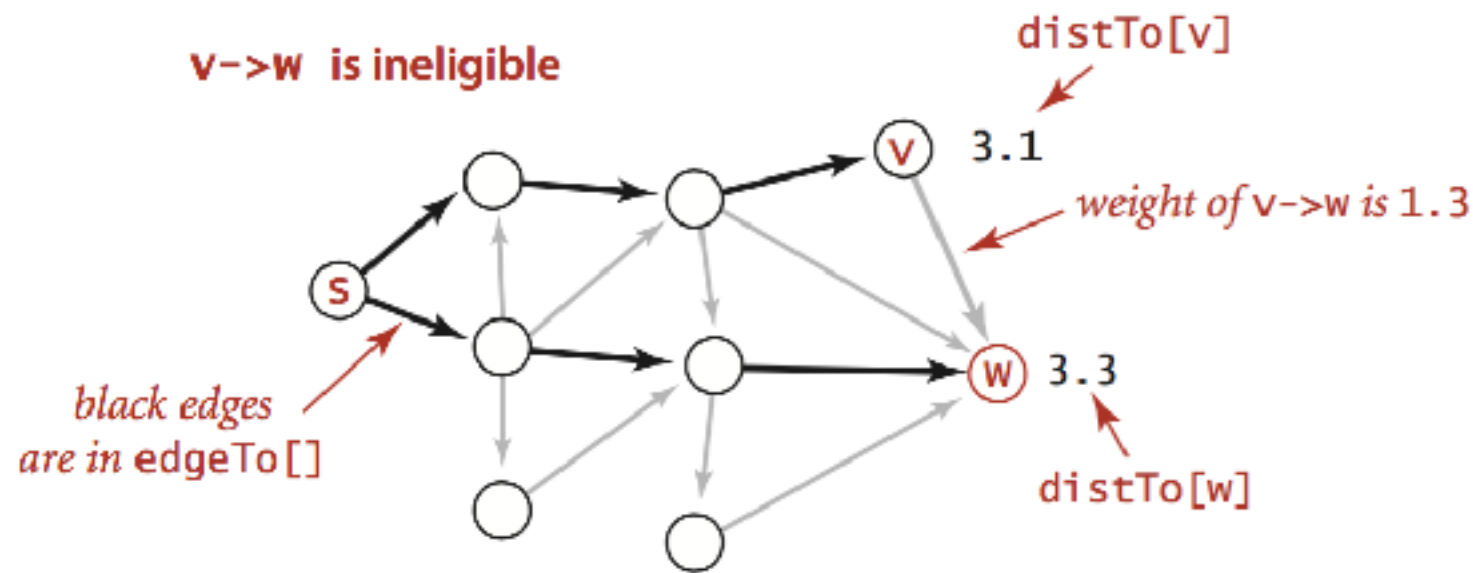

Edge relaxation

Relax edge $e = v \rightarrow w$.

- `distTo[v]` is length of shortest **known** path from s to v .
- `distTo[w]` is length of shortest **known** path from s to w .
- `edgeTo[w]` is last edge on shortest **known** path from s to w .
- If $e = v \rightarrow w$ gives shorter path to w through v ,
update both `distTo[w]` and `edgeTo[w]`.

```
private void relax(DirectedEdge e)
{
    int v = e.from(), w = e.to();
    if (distTo[w] > distTo[v] + e.weight())
    {
        distTo[w] = distTo[v] + e.weight();
        edgeTo[w] = e;
    }
}
```

Edge relaxation

Edge relaxation (two cases)

Dijkstra's algorithm visualization

Dijkstra's algorithm visualization

Dijkstra's algorithm: Java implementation

```
public class DijkstraSP
{
    private DirectedEdge[] edgeTo;
    private double[] distTo;
    private IndexMinPQ<Double> pq;

    public DijkstraSP(EdgeWeightedDigraph G, int s)
    {
        edgeTo = new DirectedEdge[G.V()];
        distTo = new double[G.V()];
        pq = new IndexMinPQ<Double>(G.V());

        for (int v = 0; v < G.V(); v++)
            distTo[v] = Double.POSITIVE_INFINITY;
        distTo[s] = 0.0;

        pq.insert(s, 0.0);
        while (!pq.isEmpty())
        {
            int v = pq.delMin();
            for (DirectedEdge e : G.adj(v))
                relax(e);
        }
    }
}
```

← relax vertices in order
of distance from s

Dijkstra's algorithm: Java implementation

```
private void relax(DirectedEdge e)
{
    int v = e.from(), w = e.to();
    if (distTo[w] > distTo[v] + e.weight())
    {
        distTo[w] = distTo[v] + e.weight();
        edgeTo[w] = e;
        if (pq.contains(w)) pq.decreaseKey(w, distTo[w]);
        else pq.insert(w, distTo[w]);
    }
}
```

← update PQ

Dijkstra's algorithm: correctness proof

Invariant. For v in T , $\text{distTo}[v]$ is the length of the shortest path from s to v .

Pf.

- Let w be next vertex added to T .
- Let P^* be the $s \rightarrow w$ path through v .
- Consider any other $s \rightarrow w$ path P ; let x be first vertex to w .
- P is already as long as P^* as soon as it reaches x .
- Thus, $\text{distTo}[w]$ is the length of the shortest path from s to w .

Dijkstra's algorithm: Performance Guarantee

Dijkstra's algorithm uses extra space proportional to V and time proportional to $E \log V$ (in the worst case) to compute the SPT rooted at a given source in an edge-weighted digraph with E edges and V vertices.

```
public class DijkstraSP
{
    private DirectedEdge[] edgeTo;
    private double[] distTo;
    private IndexMinPQ<Double> pq;

    public DijkstraSP(EdgeWeightedDigraph G, int s)
    {
        edgeTo = new DirectedEdge[G.V()];
        distTo = new double[G.V()];
        pq = new IndexMinPQ<Double>(G.V());

        for (int v = 0; v < G.V(); v++)
            distTo[v] = Double.POSITIVE_INFINITY;
        distTo[s] = 0.0;

        pq.insert(s, 0.0);
        while (!pq.isEmpty())
        {
            int v = pq.delMin();
            for (DirectedEdge e : G.adj(v))
                relax(e);
        }
    }
}
```

Computing a spanning tree in a graph

Dijkstra's algorithm seem familiar?

- Prim's algorithm is essentially the same algorithm.
- Both are in a family of algorithms that compute a spanning tree.

Main distinction: Rule used to choose next vertex for the tree.

- Prim: Closest vertex to the **tree** (via an undirected edge).
- Dijkstra: Closest vertex to the **source** (via a directed path).

Shortest path variants

- Single source: from one vertex s to every other vertex.
- Source-Sink: from one vertex s to another t .
 - use Dijkstra's algorithm, but terminate the search as soon as t comes off the priority queue.
- All pairs: between all pairs of vertices.

```
public class DijkstraAllPairsSP
{
    private DijkstraSP[] all;

    DijkstraAllPairsSP(EdgeWeightedDigraph G)
    {
        all = new DijkstraSP[G.V()]
        for (int v = 0; v < G.V(); v++)
            all[v] = new DijkstraSP(G, v);
    }

    Iterable<Edge> path(int s, int t)
    { return all[s].pathTo(t); }

    double dist(int s, int t)
    { return all[s].distTo(t); }
}
```

Shortest paths in edge-weighted DAGs

Proposition. Topological sort algorithm computes SPT in any edge-weighted DAG in time proportional to $E + V$.

edge weights
can be negative!

Pf.

- Each edge $e = v \rightarrow w$ is relaxed exactly once (when vertex v is relaxed), leaving $\text{distTo}[w] \leq \text{distTo}[v] + e.\text{weight}()$.
- Inequality holds until algorithm terminates because:
- $\text{distTo}[w]$ cannot increase  $\text{distTo}[]$ values are monotone decreasing
- $\text{distTo}[v]$ will not change  because of topological order, no edge pointing to v will be relaxed after v is relaxed
- Thus, upon termination, shortest-paths optimality conditions hold. ■

Shortest paths in edge-weighted DAGs

```
public class AcyclicSP
{
    private DirectedEdge[] edgeTo;
    private double[] distTo;

    public AcyclicSP(EdgeWeightedDigraph G, int s)
    {
        edgeTo = new DirectedEdge[G.V()];
        distTo = new double[G.V()];

        for (int v = 0; v < G.V(); v++)
            distTo[v] = Double.POSITIVE_INFINITY;
        distTo[s] = 0.0;

        Topological topological = new Topological(G);
        for (int v : topological.order())
            for (DirectedEdge e : G.adj(v))
                relax(e);
    }
}
```

← topological order

Longest paths in edge-weighted DAGs

Formulate as a shortest paths problem in edge-weighted DAGs.

- Negate all weights.
- Find shortest paths.
- Negate weights in result.

equivalent: reverse sense of equality in relax()

Key point. Topological sort algorithm works even with negative weights.

Job Assignment: Longest paths in edge-weighted DAGs

Longest paths in edge-weighted DAGs: application

Parallel job scheduling. Given a set of jobs with durations and precedence constraints, schedule the jobs (by finding a start time for each) so as to achieve the minimum completion time, while respecting the constraints.

<i>job</i>	<i>duration</i>	<i>must complete before</i>		
0	41.0	1	7	9
1	51.0	2		
2	50.0			
3	36.0			
4	38.0			
5	45.0			
6	21.0	3	8	
7	32.0	3	8	
8	32.0	2		
9	29.0	4	6	

1. How long the duration of this project can be ?
2. How many workers are needed ?

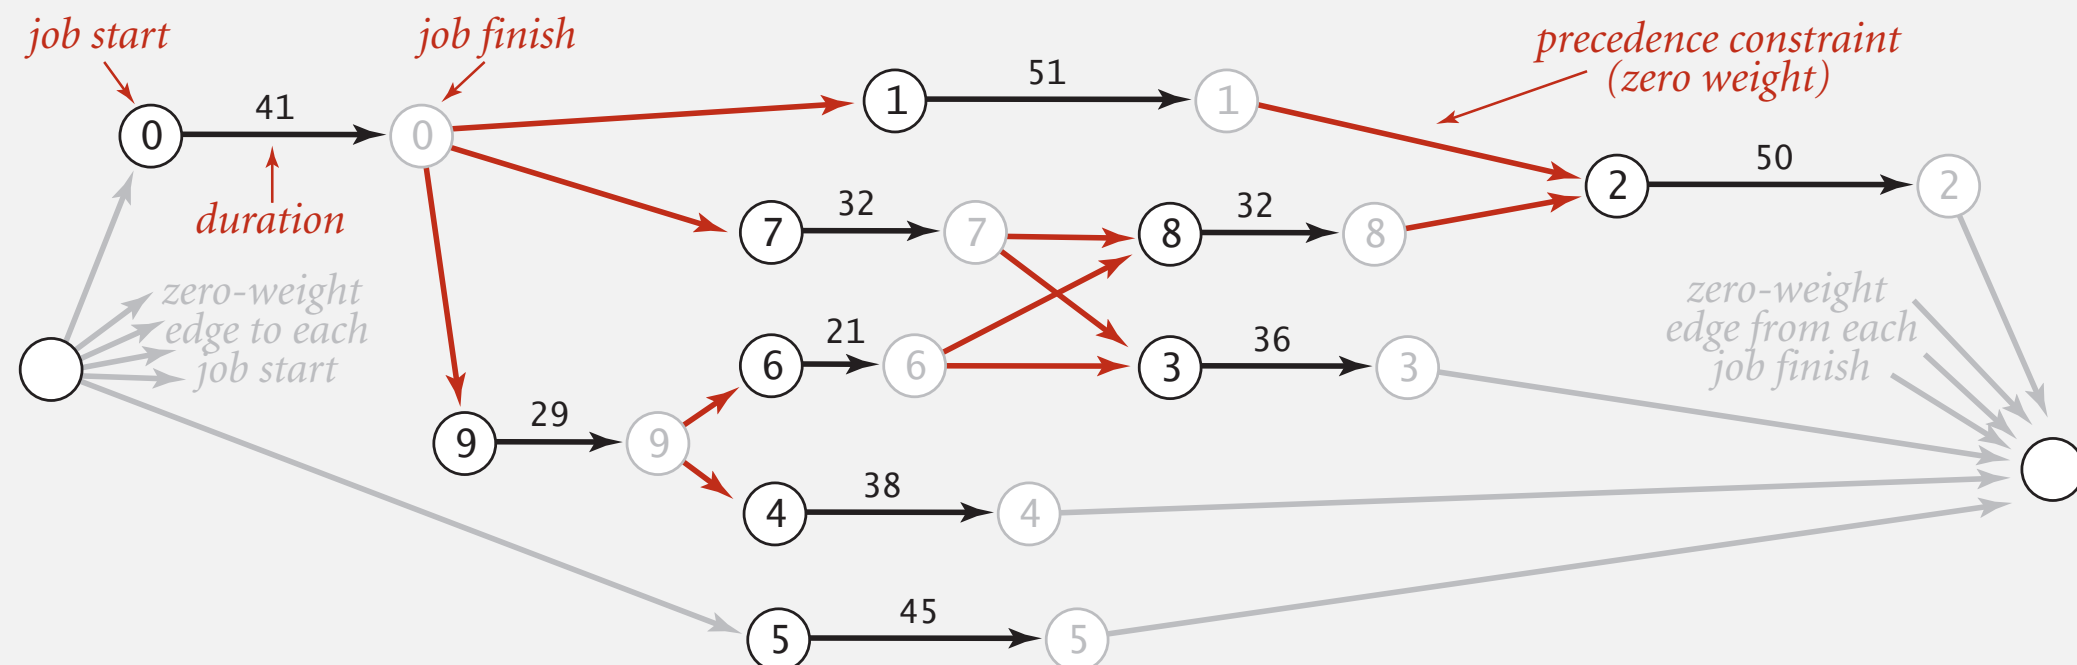

Parallel job scheduling solution

Critical path method

CPM. To solve a parallel job-scheduling problem, create edge-weighted DAG:

- Source and sink vertices.
- Two vertices (begin and end) for each job.
- Three edges for each job.
- begin to end (weighted by duration)
- source to begin (0 weight)
- end to sink (0 weight)
- One edge for each precedence constraint (0 weight).

job	duration	must complete before		
0	41.0	1	7	9
1	51.0	2		
2	50.0			
3	36.0			
4	38.0			
5	45.0			
6	21.0	3	8	
7	32.0	3	8	
8	32.0	2		
9	29.0	4	6	

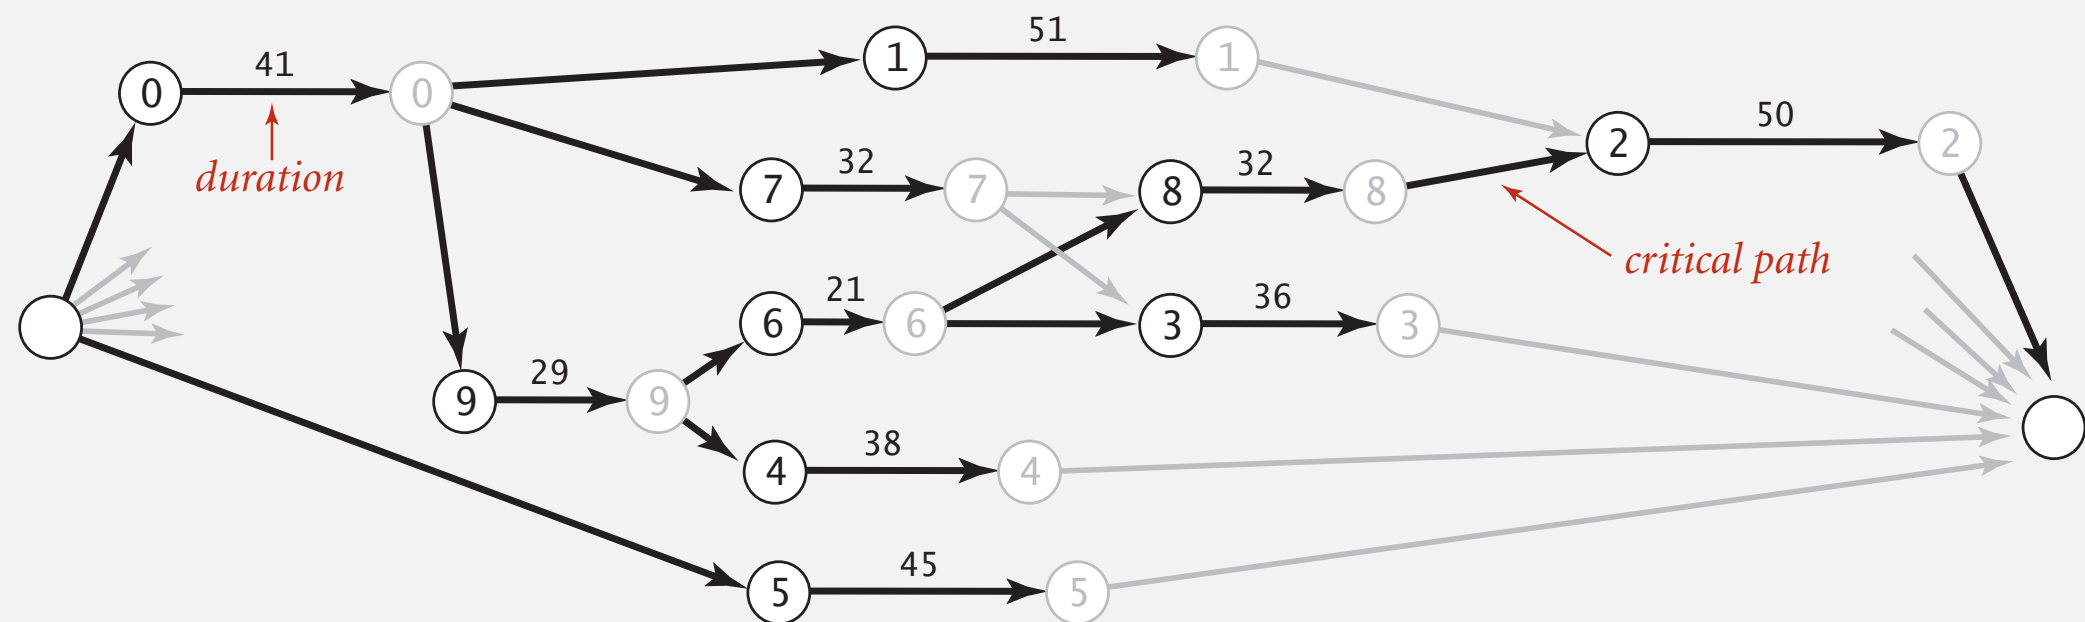

Critical path method

CPM. Use **longest path** from the source to schedule each job.

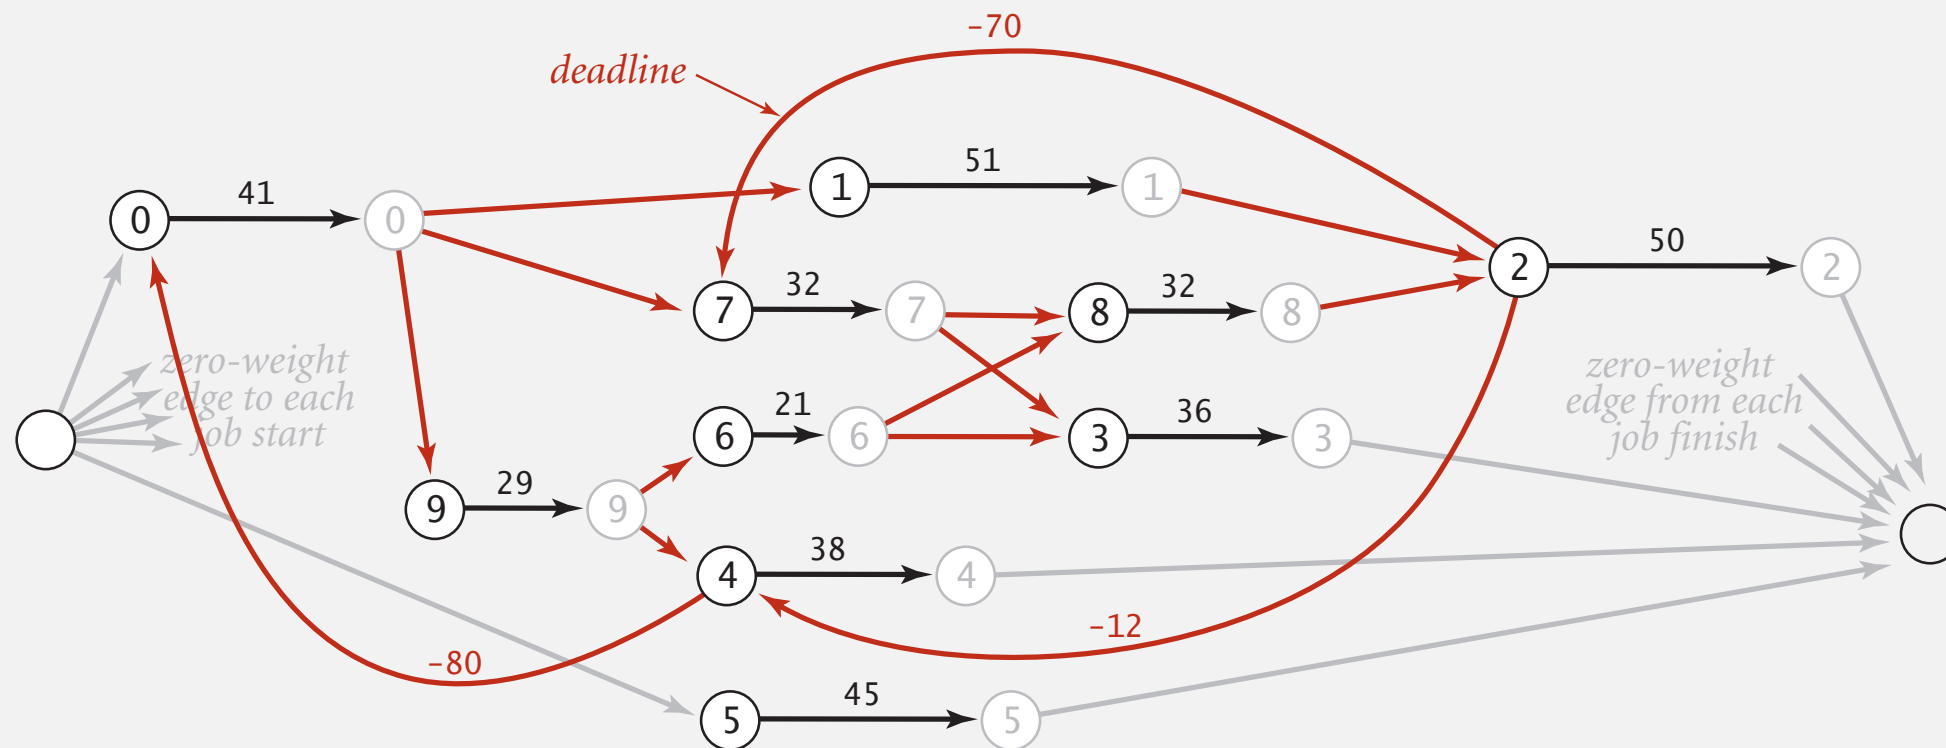

Parallel job scheduling solution

Parallel job scheduling with Deadlines

Deadlines. Add extra constraints to the parallel job-scheduling problem.

Ex. “Job 2 must start no later than 12 time units after job 4 starts.”

Consequences.

- Corresponding shortest-paths problem has cycles (and negative weights).

SHORTEST PATHS

- ▶ *shortest-paths properties*
- ▶ *Dijkstra's algorithm*
- ▶ *Edge-weighted DAGs*
- ▶ *negative weights*

Shortest paths with negative weights: failed attempts

Dijkstra. Doesn't work with negative edge weights.

Dijkstra selects vertex 3 immediately after 0.
But shortest path from 0 to 3 is $0 \rightarrow 1 \rightarrow 2 \rightarrow 3$.

Re-weighting. Add a constant to every edge weight doesn't work.

Adding 8 to each edge weight changes the
shortest path from $0 \rightarrow 1 \rightarrow 2 \rightarrow 3$ to $0 \rightarrow 3$.

Conclusion. Need a different algorithm.

Bellman-Ford algorithm for Shortest Path Problem with Negative Edges (**without Negative cycles**)

Bellman-Ford algorithm

Initialize $\text{distTo}[s] = 0$ and $\text{distTo}[v] = \infty$ for all other vertices.

Repeat V times:

- Relax each edge in **any order**.
-

```
for (int i = 0; i < G.V(); i++)  
    for (int v = 0; v < G.V(); v++)  
        for (DirectedEdge e : G.adj(v))  
            relax(e);
```

← pass i (relax each edge)

shortest-paths tree from vertex s

Bellman-Ford algorithm: analysis

Bellman-Ford algorithm

Initialize $\text{distTo}[s] = 0$ and $\text{distTo}[v] = \infty$ for all other vertices.

Repeat V times:

- Relax each edge.**
-

Pf idea. After pass i , found shortest path to each vertex v for which the shortest path from s to v contains i edges (or fewer).

Bellman-Ford algorithm: queue-based implementation

Observation. If `distTo[v]` does not change during pass i , no need to relax any edge pointing from v in pass $i+1$.

FIFO implementation. Maintain **queue** of vertices whose `distTo[]` changed.

Overall effect.

- The running time is still proportional to $E \times V$ in worst case.
- But much faster than that in practice ($E + V$).

Trace of the Bellman-Ford algorithm

Example 1

4→5	0.35
5→4	0.35
4→7	0.37
5→7	0.28
7→5	0.28
5→1	0.32
0→4	0.38
0→2	0.26
7→3	0.39
1→3	0.29
2→7	0.34
6→2	-1.20
3→6	0.52
6→0	-1.40
6→4	-1.25

SPT

Bellman-Ford algorithm: Java implementation

```
public class BellmanFordSP
{
    private double[] distTo;
    private DirectedEdge[] edgeTo;
    private boolean[] onQ;
    private Queue<Integer> queue;

    public BellmanFordSPT(EdgeWeightedDigraph G, int s)
    {
        distTo = new double[G.V()];
        edgeTo = new DirectedEdge[G.V()];
        onQ = new boolean[G.V()];
        queue = new Queue<Integer>();

        for (int v = 0; v < V; v++)
            distTo[v] = Double.POSITIVE_INFINITY;
        distTo[s] = 0.0;

        queue.enqueue(s);
        while (!queue.isEmpty())
        {
            int v = queue.dequeue();
            onQ[v] = false;
            for (DirectedEdge e : G.adj(v))
                relax(e);
        }
    }
}
```

queue of vertices whose
distTo[] value changes

```
private void relax(DirectedEdge e)
{
    int v = e.from(), w = e.to();
    if (distTo[w] > distTo[v] + e.weight())
    {
        distTo[w] = distTo[v] + e.weight();
        edgeTo[w] = e;
        if (!onQ[w])
        {
            queue.enqueue(w);
            onQ[w] = true;
        }
    }
}
```

Single source shortest-paths implementation: cost summary

algorithm	restriction	typical case	worst case	extra space
topological sort	no directed cycles	$E + V$	$E + V$	V
Dijkstra (binary heap)	no negative weights	$E \log V$	$E \log V$	V
Bellman–Ford	no negative cycles	$E V$	$E V$	V
Bellman–Ford (queue-based)		$E + V$	$E V$	V

Remark 1. Directed cycles make the problem harder.

Remark 2. Negative weights make the problem harder.

Remark 3. Negative cycles makes the problem intractable.

Negative cycles

Def. A **negative cycle** is a directed cycle whose sum of edge weights is negative.

digraph

4→5	0.35
5→4	-0.66
4→7	0.37
5→7	0.28
7→5	0.28
5→1	0.32
0→4	0.38
0→2	0.26
7→3	0.39
1→3	0.29
2→7	0.34
6→2	0.40
3→6	0.52
6→0	0.58
6→4	0.93

negative cycle $(-0.66 + 0.37 + 0.28)$

5→4→7→5

shortest path from 0 to 6

0→4→7→5→4→7→5...→1→3→6

Proposition. A SPT exists iff no negative cycles.

assuming all vertices reachable from s

Finding a negative cycle

Negative cycle. Add two methods to the API for SP.

boolean hasNegativeCycle() *is there a negative cycle?*

Iterable <DirectedEdge> negativeCycle() *negative cycle reachable from s*

digraph

4->5 0.35
5->4 -0.66
4->7 0.37
5->7 0.28
7->5 0.28
5->1 0.32
0->4 0.38
0->2 0.26
7->3 0.39
1->3 0.29
2->7 0.34
6->2 0.40
3->6 0.52
6->0 0.58
6->4 0.93

negative cycle $(-0.66 + 0.37 + 0.28)$

5->4->7->5

Finding a negative cycle

Observation. If there is a negative cycle, Bellman-Ford gets stuck in loop, updating `distTo[]` and `edgeTo[]` entries of vertices in the cycle.

Proposition. If any vertex v is updated in pass v , there exists a negative cycle (and can trace back `edgeTo[v]` entries to find it).

In practice. Check for negative cycles more frequently.

Negative cycle application: arbitrage detection

Problem. Given table of exchange rates, is there an arbitrage opportunity?

	USD	EUR	GBP	CHF	CAD
USD	1	0.741	0.657	1.061	1.011
EUR	1.35	1	0.888	1.433	1.366
GBP	1.521	1.126	1	1.614	1.538
CHF	0.943	0.698	0.62	1	0.953
CAD	0.995	0.732	0.65	1.049	1

Ex. \$1,000 \Rightarrow 741 Euros \Rightarrow 1,012.206 Canadian dollars \Rightarrow 
\$1,007.14497. $1000 \times 0.741 \times 1.366 \times 0.995 = 1007.14497$

Negative cycle application: arbitrage detection

Currency exchange graph.

- Vertex = currency.
- Edge = transaction, with weight equal to exchange rate.
- Find a directed cycle whose product of edge weights is > 1 .

$$0.741 * 1.366 * .995 = 1.00714497$$

Challenge. Express as a negative cycle detection problem.

Shortest paths summary

Nonnegative weights.

- Arises in many applications.
- Dijkstra's algorithm is nearly linear-time.

Acyclic edge-weighted digraphs.

- Arise in some applications.
- Topological sort algorithm is linear time.
- Edge weights can be negative.

Negative weights and negative cycles.

- Arise in some applications.
- If no negative cycles, can find shortest paths via Bellman-Ford.
- If negative cycles, can find one via Bellman-Ford.

Shortest-paths is a broadly useful problem-solving model.
